

what  
is  
slop-  
ware

,  
how  
do  
you  
spot  
it,  
what  
do  
you  
do?

a cur-  
riculum  
that  
teaches  
you to  
measure  
the dis-  
tance  
between  
some-  
thing  
that  
looks  
like it  
works  
and  
some-  
thing  
that ac-

tually  
holds  
up.  
every  
chapter  
ends  
with a  
check  
you run  
on your  
own  
project.

00 why  
does  
this  
book  
exist?

01 what  
is the  
thing  
on your  
screen?

02 why  
can  
your

deploy  
not  
find  
your  
files?

03 why  
does  
your  
link  
only  
open  
for  
you?

04  
what  
is the  
dif-  
fer-  
ence  
be-  
tween  
npm  
run  
dev  
and  
npm  
run  
build?

05 why  
does  
the  
till  
stand  
in a  
dif-

ferent  
room?

00

# why does this book ex- ist?

Why this  
book ex-  
ists,  
who is  
writing  
it, and  
how to  
read it.

---

I have  
been using  
forums  
such as  
Reddit,  
Quora and  
Ekşi  
Sözlük for  
years, and  
once I was  
one of the  
people  
posting  
there.  
People  
make fun  
of local-  
host:3000  
users, and  
they be-

lieve CS is  
dead be-  
cause  
somebody  
developed  
a local  
website.

Actually, I  
hate need-  
less jokes  
made just  
to fit in.  
But also,  
lack of  
technical  
depth gave  
those lo-  
calhost:30  
00 owners  
the  
courage of  
a super-  
hero. So  
instead of  
joining in,  
I decided  
to create a  
blog about  
how to  
avoid slop-  
ware,  
based on  
my own  
experi-  
ences.

Learnin  
g it cost  
me 53 re-  
pos, 8 pull  
requests  
and 6

Claude  
Max x20  
accounts.  
It also  
cost me  
exploding  
token bills,  
sleepless  
nights,  
and the 5  
kilos I lost  
to hunger  
and lack  
of sleep. I  
do not  
want that  
to happen  
to any-  
body else,  
and I do  
not want a  
power this  
large to  
stay hid-  
den inside  
one class  
of people.  
I am using  
Claude  
while I  
write this,  
and I am  
sure Dario  
Amodei  
would  
want the  
same. So I  
am writing  
it with my  
own  
hands, out

of every-  
thing I  
pulled  
from my  
own pain.

I do  
not believe  
that CS  
has been  
replaced  
by AI.\*  
Over time  
there was  
COBOL  
and C++  
did not re-  
place it,  
Java did  
not re-  
place  
C++, and  
Python  
did not re-  
place  
Java.

Given the  
nature of  
high level  
languages,  
I treat an  
LLM as  
one more  
high level  
language.

(And  
where has  
engineer-  
ing gone?  
Engineerin  
g is the

difference  
in the  
thinking  
itself, in  
knowing  
what to  
make and  
in con-  
necting  
technolo-  
gies and  
developing  
them.)

I love  
vibecod-  
ing

Tony  
Stark is a  
vibecoder  
with un-  
limited to-  
kens. As  
far as I  
see, in-  
ternships  
and  
projects  
are pre-  
sented as  
though  
they be-  
long to  
certain  
people.  
What gets  
inherited  
is not only

money.

You can  
call it in-  
herited vi-  
sion, you  
can call it  
social  
climbing,  
and there  
is even a  
niche for it  
now,  
something  
like a class  
based net-  
working  
hub  
founder.

What will  
happen  
soon is  
that some-  
body  
starts a  
business  
with a  
Claude

Pro ac-  
count and  
has gradu-  
ates of  
good  
schools  
working  
under-  
neath  
them,  
when  
those same  
students  
could have

started  
that com-  
pany with  
their  
pocket  
money.  
Neverthele  
ss, if it is  
not rocket  
science  
and it is  
not tank  
design, I  
do not  
think any  
work that  
needs no  
large capi-  
tal is as  
big and as  
irreplace-  
able as it  
is claimed  
to be.  
Your ap-  
plication  
was reject-  
ed, so say  
that you  
could do  
this too  
and carry  
on your  
way.

Everyo  
ne should  
benefit  
from tech-  
nology,  
and not  
only for

business  
and mon-  
ey, but for  
making  
products  
for your  
own needs.  
As I be-  
lieve from  
Plato, no  
one does  
wrong  
willingly,  
and no-  
body  
writes bad  
software  
on pur-  
pose ei-  
ther.  
Outside  
academic  
purposes,  
CS is no  
different  
from being  
able to  
sew a but-  
ton on.  
Everyone  
should  
learn it in  
order to  
make the  
ideas they  
dream of  
real, and  
most im-  
portantly,  
everyone  
can, be-

cause I believe that  
for once in history  
anyone can build  
anything.

What matters is  
whether anything  
stands behind the  
code.

Think about the  
last time your terminal  
told you every test  
passed. It told you  
that some tests ran  
and none of them  
complained,  
and nothing about  
whether they would  
have noticed a  
broken app.

Who am  
I?

I am  
Damla, a  
CS stu-  
dent at  
Bilkent. I  
was on the  
board of  
IEEE, I  
worked as  
a Python  
assistant, I  
did an in-  
ternship  
and a fel-  
lowship,  
and the  
rest is on  
my CV.

Actual-  
ly I was a  
coder be-  
fore CS  
took over,  
starting  
with  
HTML at  
11 and a  
lot of  
Stack  
Overflow.  
Now I  
vibecode  
anyway.  
(Okay,  
what I re-  
ally do is  
LLM sys-

tems engi-  
neering,  
which  
means I  
connect  
systems  
and engi-  
neer  
them.)

ir-globe  
draws  
what 198  
countries  
do to each  
other and  
it has  
been going  
for months  
without  
me touch-  
ing it, on  
in-  
frastruc-  
ture that  
costs 0  
dollars a  
month.  
stitchu  
takes a  
photo-  
graph of a  
garment  
and gives  
back a  
sewing  
pattern,  
and it has  
a gate  
that de-  
cides  
whether

that pat-  
tern can  
actually  
be sewn,  
which I  
wrote af-  
ter print-  
ing pat-  
terns that  
passed  
every test  
I had and  
could not  
be sewn at  
all. lu-  
lumelon  
measures  
what lan-  
guage  
models say  
about a  
brand and  
prints a  
range  
rather  
than a sin-  
gle num-  
ber, be-  
cause on  
its first  
live run  
the honest  
interval  
ran from 0  
to 33,3.  
rabadon is  
a gate sys-  
tem for  
agents,  
written in  
C++ with

no dependencies,  
and it exists because an agent once told me it had finished a job it had not finished.

Each of those started as something I got wrong, then found, then fixed, and the fix is what this book hands over.

How should you read this book?

The order is semantic, and I spent a full week reading and think-

ing before  
I settled  
it. I started  
from  
localhost,  
because  
that is the  
joke I kept  
seeing.

Writing it  
made me  
realise the  
link only  
fails if you  
believe a  
page is a  
place, so  
that subject  
had to  
come first.

Writing  
that one  
made me  
realise I  
was talking  
about  
files without  
ever  
saying

what a  
folder is,  
so the terminal  
came next.

Localhost  
then required  
npm run  
dev, because  
once you know

whose machine answers you want to know what is running on it. That one required npm run build, because the thing you would put on another machine is not the thing running on yours. After that came the backend, because a program on another machine is what the whole book has been walking towards. The backend required data, because a backend keeps something.

Data re-  
quired  
.env files  
and API  
keys, be-  
cause the  
moment  
something  
is kept,  
whatever  
reaches it  
matters.

Those  
chapters  
are  
grouped  
into five  
parts. 101  
is what  
you are  
actually  
holding.  
201 gets  
your  
project off  
your own  
computer.  
301 is  
where real  
users and  
real at-  
tackers ar-  
rive, 401 is  
the part  
people  
touch, and  
501 is  
money.  
Afterward  
s I will  
write

about  
LLM sys-  
tem de-  
sign, or-  
chestra-  
tion,  
loops,  
workflows  
and gates.

Every  
chapter  
opens with  
a real inci-  
dent and  
closes with  
the thing  
you can do  
tomorrow,  
on your  
own  
project. I  
don't want  
to stretch  
the sched-  
ule be-  
cause 2  
months in  
tech = 10  
years of  
develop-  
ment in  
any topic.

By the  
way, new  
tabs keep  
opening in  
my head,  
and a  
chapter  
about one  
thing

wakes up  
an idea  
about  
something  
else entirely.  
Those  
ideas do  
not belong  
inside the  
chapter, so  
they go in  
the appendix,  
and terms  
and small  
technical  
things  
that do  
not fit  
there go in  
the foot-  
notes.  
Both sit at  
the bottom  
of the page,  
so anything  
marked  
with a star  
has a note  
waiting for  
it.

The appendix  
is also where  
the writing  
about product  
management  
and the start-

up world  
will go.  
Companies  
still run  
events to  
hand out  
the kind of  
knowledge  
you can  
only get  
through  
experi-  
ence, and  
then they  
turn cre-  
ative peo-  
ple away  
with rea-  
sons on  
the level  
of you are  
a Gemini,  
that is  
why you  
were elimi-  
nated. To  
tell you  
the truth,  
I do not  
think any-  
body is as  
well inten-  
tioned as I  
am, and  
people  
hold a  
strange  
principle  
about not  
sharing  
good

things.

You can  
steal my  
ideas.

There is  
sand in  
the sea  
and there  
are ideas  
in me, so  
passing on  
what I  
know is  
nothing  
but a hap-  
piness for  
me.

Thanks

Years ago  
the yazbel  
documen-  
tation  
made me  
interested  
in comput-  
er science,  
and I  
changed  
my de-  
partment.  
Even  
though we  
have not  
been writ-  
ing code  
by hand  
for the

last year,  
it gave me  
a love of  
CS that  
no under-  
graduate  
degree  
could have  
given me.  
We used  
to shorten  
loops with  
algorithm  
analysis,  
and now  
we do the  
same thing  
inside  
workflows.  
The lan-  
guage  
changed  
and the  
tool  
changed,  
while the  
purpose  
and the  
logic did  
not, so I  
still think  
this mo-  
tion in CS  
is a matter  
of  
perspec-  
tive.

So  
when I am  
no longer  
a sweet

student  
but a busi-  
ness-  
woman, I  
hope this  
book will  
have en-  
lightened  
somebody,  
enter-  
tained  
somebody,  
or made  
somebody  
think.

Two  
heads are  
better  
than one,  
so whatev-  
er work  
you are in,  
try your  
own idea  
too. My  
endless re-  
spect to  
everyone  
who is  
dreaming  
and work-  
ing for  
something.

---

\* Is CS  
dead?  
The  
claim

is  
usual-  
ly  
made  
about  
a lan-  
guage  
, not  
about  
the  
field.  
COB  
OL  
was  
going  
to be  
re-  
place  
d by  
C++,  
C++  
by  
Java,  
Java  
by  
Pytho  
n,  
and  
every  
one of  
them  
is still  
run-  
ning  
some-  
where  
right  
now.  
What

chang  
ed  
each  
time  
was  
the  
height  
of the  
lan-  
guage  
, not  
wheth  
er  
some-  
body  
had  
to de-  
cide  
what  
to  
build.

# what is the thin g on your scree n?

A page  
is not a  
place.  
It is a  
delivery  
that  
happens  
again  
every  
time  
somebody  
looks.

---

The first  
thing you  
do with a  
coding  
agent is  
ask it for a  
website,  
and a  
minute  
later there  
is one.  
The termi-  
nal prints  
an ad-

dress. You  
open it  
and the  
thing you  
described  
is sitting  
in the  
browser  
looking  
finished.

Ask  
where that  
thing lives  
and the  
answer  
comes  
back as in  
the brows-  
er or on  
my com-  
puter or  
on the in-  
ternet. All  
three feel  
fine right  
up until  
something  
breaks,  
and then  
none of  
them tell  
you where  
to look.<sup>1</sup>

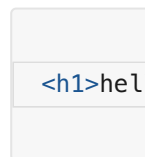

---

<sup>1</sup>  
**A book  
note.** A  
model takes  
the easiest  
road. It

gave you localhost  
with no  
backend,  
because  
that is the  
shortest  
way to  
something  
that runs.

What arrives  
when a  
page  
opens?

Make a  
folder anywhere  
you like and  
put a single  
file in it  
called  
index.html  
with one  
line inside.

Open a  
terminal  
in that  
folder and  
run  
python3 -  
m  
http.server  
8000. Go  
to local-

host:8000  
in your  
browser.  
The word  
hello is  
there in  
large let-  
ters, arriv-  
ing from a  
server  
small  
enough  
that noth-  
ing can  
hide inside  
it.

Now  
right click  
on the  
page and  
choose  
view  
source.  
What  
comes up  
is the line  
you typed,  
character  
for  
character.

Change  
the h1 to  
a p and  
refresh.  
The same  
word  
comes  
back  
small.  
Nobody  
sent you a

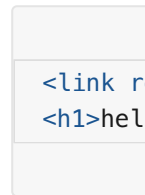

smaller  
word. You  
changed  
one in-  
struction  
and the  
browser  
drew the  
letters dif-  
ferently,  
because  
what trav-  
elled to it  
was never  
a page. It  
was a set  
of instruc-  
tions for a  
program  
that car-  
ries them  
out.

How does  
the  
browser  
learn  
about the  
second  
file?

One file is  
not how  
anything  
real ar-  
rives. Next  
to in-  
dex.html  
make a file

called  
style.css  
containing  
h1 { color:  
crimson; }  
and men-  
tion it  
from the  
page.

Refresh  
and the  
word is  
red.

Your  
browser  
had no  
way of  
knowing  
that  
style.css  
existed.  
The only  
file it had  
been given  
was in-  
dex.html.

It read  
that file  
and came  
to a line  
mention-  
ing a  
stylesheet.

Only then  
did it go  
back to  
the server

for a second file.  
The page tells the browser what else to fetch, one discovery at a time.

Open the developer tools with Cmd and Option and I on a Mac or F12 on Windows. Click the Network tab and refresh with the panel open. Two rows come up, index.html first and style.css second, and they can never come in the other order.

A slow page is rarely one

slow file.  
The document arrives and mentions something.  
That something arrives and mentions two more.  
Nothing further down the chain starts until the thing before it has been read.

Where does the page go when the server stops?

'The page is on my computer, so it will still be there,' you may be thinking.  
In the Network

panel  
there is a  
checkbox  
marked  
Disable  
cache.  
Tick it so  
the brows-  
er stops  
keeping  
copies of  
its own.  
Now go to  
the termi-  
nal and  
stop the  
server  
with Ctrl  
and C,  
then re-  
fresh the  
page.

The  
page is  
gone and  
there is no  
error  
about  
your  
HTML,  
because  
your  
HTML  
never ar-  
rived.  
Nothing  
had been  
sitting in  
the brows-  
er waiting  
for you.

Start  
the server  
again and  
refresh.  
Hello  
comes  
back in  
red exact-  
ly as be-  
fore,  
drawn  
from noth-  
ing. A  
page is a  
delivery  
that hap-  
pens again  
every time  
somebody  
looks.

What  
does this  
look like  
in a real  
project?

Open the  
project  
you have  
been  
working  
on and re-  
fresh it  
with the  
panel  
open. The  
same list  
appears,

only far  
longer.

The document sits  
at the top.  
Everything  
g the document  
mentioned  
sits under  
it, and under  
those  
sits everything  
they mentioned  
in turn.

At the  
bottom of  
the panel  
there is a  
total size.  
Every visitor  
downloads that  
much before  
they see  
anything at  
all, out of  
their connection  
and their  
phone  
plan.

That  
leaves one  
question  
for the  
rest of the  
book.  
Some pro-

gram on  
some ma-  
chine sent  
those files.  
On the  
hello page  
you know  
which one,  
because  
you start-  
ed it your-  
self and it  
is still sit-  
ting in  
your ter-  
minal. On  
your real  
project  
you have  
probably  
never  
thought  
about it.

☐ my  
project  
passes  
this  
check

You just  
started a  
server in-  
side a  
folder  
without  
my having  
said what  
a folder is,  
and that  
gap has to  
close be-  
fore we  
can ask  
whose ma-  
chine your  
files come  
from. So  
the termi-  
nal and  
the folder  
come next.

# why can your de- ploy not find your files?

The same  
command  
run one  
level up  
serves  
nothing.  
Most de-  
ploy  
failures  
start  
here.

---

You ran a  
command  
inside a  
folder a  
moment  
ago and a  
server ap-  
peared,  
and I nev-  
er said  
which  
folder it  
was read-

ing or why  
that mat-  
tered. The  
same com-  
mand run  
from one  
step high-  
er up  
would  
have  
served  
nothing.

A  
whole  
family of  
failures  
comes out  
of that.  
The build  
that works  
on your  
machine  
and re-  
turns file  
not found  
on the de-  
ploy is  
one, the  
image that  
loads lo-  
cally and  
404s in  
production  
is another.  
In every  
one of  
them a  
program is  
standing  
somewhere  
you did

not expect, reading a path that means something different from there.

Where are you standing?

Open a terminal.  
On a Mac it is called Terminal.  
On Windows, use the one your development tools installed rather than the old black box.

A command never runs in general. It runs while you are standing somewhere and where

you are  
standing  
changes  
what it  
does.

```
pwd
```

Print  
working  
directory.  
It answers  
with the  
absolute  
path of  
where you  
are stand-  
ing right  
now.

```
ls -F
```

Plain `ls`  
lists files  
and fold-  
ers togeth-  
er with no  
way to tell  
them  
apart, and  
`-F` puts a  
slash on  
the end of  
every fold-  
er name.  
Do not try  
to work it  
out from  
the name.  
README

has no dot  
and is a  
file, while  
a folder  
called  
backup.old  
has one  
and is still  
a folder.

Change di-  
rectory,  
into the  
Desktop  
that sits  
inside  
wherever  
you al-  
ready are.  
Run `pwd`  
again and  
the answer  
has grown  
by one  
step. Run  
`ls -F` and  
the con-  
tents have  
changed,  
because  
the same  
command  
means  
something  
different  
here.

Two dots is a real entry that exists inside every folder on the disk and it points at that folder's parent.

That is the whole of navigation.

Three commands and one convention, and they work the same way on every Mac and every Linux machine and inside the terminal your Windows tools installed.

Is the terminal a different place?

If the terminal still feels like a second machine hiding underneath the one you use, open Finder or Explorer and go to your project folder. Put that window on one side of your screen and the terminal on the other. Now cd your way to the same folder and run ls -F.

They are the same thing. The icons on

the left  
and the  
names on  
the right  
are one  
folder de-  
scribed in  
two ways,  
and the  
three com-  
mands you  
just  
learned  
will reach  
any folder  
on the  
disk.

What is a  
path?

A folder  
holds files  
and other  
folders  
and those  
hold more.  
All of it  
hangs  
down from  
one start-  
ing point,  
so your  
whole disk  
is a single  
tree.

A path  
is direc-  
tions

through  
that tree  
and pwd  
printed  
one of  
them.

```
/Users/c
```

It means  
start at  
the top of  
the disk  
and go  
into Users,  
then into  
damla and  
Desktop  
and  
project.

Each slash  
is a door  
you walk  
through.

A postal  
address is  
written  
the same  
way and a  
path is  
that writ-  
ten on one  
line.

There  
are two  
kinds.

```
/Users/c  
style.cs
```

The absolute one begins with a slash and is measured from the top of the disk, so it means the same file wherever you use it. The relative one is measured from where you are standing, so those same characters point at different files depending on where they are read.

Why is this so hard to learn?

Go back to the folder with

index.html  
and  
style.css in  
it and  
start the  
server  
again. The  
page loads  
and the  
word is  
red. Now  
stop the  
server, run  
`cd ..` to  
step up  
one level,  
and start  
it again  
from  
there.

A terminal window with a light gray background. It contains two lines of blue text: `cd ..` on the first line and `python3` on the second line.

Open lo-  
calhost:80  
00. There  
is no page,  
only a list  
of folder  
names.  
Nothing  
was moved  
and noth-  
ing was  
deleted.  
The href  
inside your  
HTML  
still says  
style.css

and it still  
means the  
style.css  
next to  
me, and  
the server  
is now  
standing  
one level  
up where  
no such  
file sits.  
Your  
whole  
project is  
intact and  
unreach-  
able.

That is  
the entire  
failure,  
and here is  
why it  
stays in-  
visible un-  
til it costs  
you a day.  
A few  
years ago  
lecturers  
in physics  
and engi-  
neering  
started  
running  
into some-  
thing they  
could not  
explain.  
They  
would ask

a class to  
open a file  
from a  
particular  
directory.

We as stu-  
dents usu-  
ally strug-  
gle to do  
exactly  
that, my-  
self includ-  
ed, even  
though we  
use a com-  
puter all  
day and  
use it well.

A file  
lives in the  
app or on  
the com-  
puter, and  
the way  
you reach  
it is to  
search for  
it.

That  
model  
works for  
daily life.  
Put every-  
thing in  
one pile  
and search  
when you  
need  
something.  
You will  
find your

holiday  
pho-  
tographs  
every  
time. It  
stops  
working at  
the deploy,  
because  
the ma-  
chine you  
deploy to  
has no  
search  
box. It is  
handed a  
path and  
goes ex-  
actly  
there. If  
nothing is  
there it  
stops.

Directo-  
ry struc-  
ture is so  
ordinary  
to the  
people  
who know  
it that  
words for  
it are hard  
to find, so  
nobody  
explains it  
and no-  
body asks.

Why does  
this de-  
cide  
whether  
things  
work?

Every  
build step,  
every de-  
ploy tool  
and every  
error mes-  
sage you  
will read  
for the  
rest of  
your life  
assumes  
you know  
where you  
are  
standing.

File  
does not  
exist al-  
most al-  
ways  
means a  
relative  
path was  
read from  
a folder  
you were  
not ex-  
pecting.  
The file  
was there  
all along,  
and the

program  
was stand-  
ing some-  
where else  
when it  
went look-  
ing for it.  
You saw  
exactly  
that a  
minute  
ago with a  
server one  
level too  
high.

    Someth-  
ing works  
on your  
machine  
and dies  
on the de-  
ploy for  
the same  
reason.

You typed  
the com-  
mand  
while  
standing  
inside the  
project  
folder.

The other  
machine  
runs it  
while  
standing  
wherever  
it happens  
to start, so  
the rela-

tive path  
points at a  
place that  
does not  
exist.

Chapter  
16 is  
where this  
bites  
hardest.

MIT  
teaches a  
free course  
for exactly  
this gap  
called The  
Missing  
Semester  
of Your  
CS  
Education.  
Julia  
Evans  
draws  
comics  
about the  
shell that  
are the  
friendliest  
thing on  
the  
subject.

☐ my  
project  
passes  
this  
check

Next  
comes lo-  
calhost,  
and the  
reason a  
link that  
opens in-  
stantly for  
you does  
not open  
for your  
friend.

why  
does  
your  
link  
only  
open  
for  
you?

Your ma-  
chine  
answers  
its own  
name.

Your  
friend's  
machine  
answers  
its own,  
and  
finds  
nothing.

---

This chap-  
ter is  
about fa-  
mous lo-  
calhost:30  
00. Jokes  
about it  
have been  
going  
around the  
internet  
for a long  
time.

Many people believe CS is dead because they built a website hosting on local. You click your own link and it opens. Your friend clicks it and it does not. Why does it happen, what is localhost:3000, and how to fix this issue?

What does localhost mean?

It begins with localhost:3000 or 127.0.0.1:3000, which are the same address writ-

ten two  
ways. lo-  
calhost is  
a name  
and  
127.0.0.1  
is the  
number  
the name  
stands for.  
RFC 6761  
reserves  
both for  
one pur-  
pose, and  
that pur-  
pose is to  
mean the  
computer  
that is  
asking.  
When you  
type it,  
your ma-  
chine  
sends the  
request to  
a program  
on itself.  
The re-  
quest nev-  
er leaves  
the ma-  
chine,  
which is  
why this is  
called the  
loopback  
address.  
When  
your

friend  
types it,  
their machine  
sends the  
request to  
a program  
on itself  
and finds  
none.

Each computer's localhost is  
a different  
server.

The  
number after  
the  
colon is  
the port.  
If the address  
is  
the building,  
the  
port is the  
apartment  
inside it.

One machine runs  
many programs and  
each waits  
at its own  
number.

3000 is a  
convention  
development tools  
picked,  
nothing  
more. The

port is  
fine. The  
building is  
the prob-  
lem, be-  
cause you  
gave your  
friend the  
name  
every  
building  
uses for  
itself.

Can your  
own  
phone  
open it?

Open the  
terminal  
and cd  
into any  
folder that  
has a file  
or two in  
it. Run  
this.

A terminal window with a light gray background. The text 'python3' is displayed in a blue monospace font, indicating it has been entered as a command.

This starts  
a small  
web  
server.

The flag  
tells it to  
answer  
only the

machine it  
is running  
on. Open  
localhost:8  
000 in the  
browser  
and you  
see the  
folder's  
files listed.  
Now type  
the same  
address  
into your  
phone's  
browser.  
Nothing  
comes  
back, even  
though the  
phone is  
on the  
same wifi.  
The phone  
went look-  
ing for a  
program  
at port  
8000 on  
itself.

Now  
stop the  
server  
with  
Ctrl+C  
and start  
it again  
without  
the flag.

The flag  
was doing  
all the  
work.

127.0.0.1  
told the  
server to  
listen on  
the loop-  
back ad-  
dress

alone, so  
requests  
arriving  
over wifi  
were never  
answered.

Without  
the flag  
this tool  
listens on  
0.0.0.0,  
which is  
not an ad-  
dress you  
connect

to. It  
means

every net-  
work in-  
terface the  
machine

has, in-  
cluding  
the wifi  
card. A re-  
quest from

the phone  
is now ac-  
cepted the  
same as  
one from  
the ma-  
chine it-  
self. You  
will see  
0.0.0.0  
again in  
Docker  
logs and in  
cloud de-  
ploy out-  
put and it  
always  
means the  
same  
thing.

Now  
find the  
laptop's  
address on  
the local  
network.  
On a Mac  
that is ip-  
config  
getifaddr  
en0 and  
on Linux  
hostname  
-I. It looks  
like  
192.168.1.  
24. If the  
Mac com-  
mand  
comes  
back emp-

ty your  
wifi is on  
another  
interface,  
so try en1.  
Type  
http://192  
.168.1.24:8  
000 into  
the phone  
and the  
file list ap-  
pears.  
Nothing in  
the files  
changed,  
only which  
doors the  
program  
answers  
and which  
machine  
the phone  
was told  
to look at.

How far  
does the  
local net-  
work  
reach?

'So I drop  
the flag  
and I am  
live,' you  
may be  
thinking.  
What you

have is a  
server  
reachable  
from the  
same wifi.  
192.168.1.  
24 is an  
address in-  
side your  
home net-  
work and  
means  
nothing  
outside it,  
so a friend  
in a cafe  
or a cus-  
tomer on  
mobile  
data can-  
not reach  
it. And  
when the  
laptop lid  
closes,  
nothing is  
running  
anywhere.

A prod-  
uct has to  
answer  
while you  
are asleep,  
so the pro-  
gram has  
to run on  
a machine  
that stays  
on and has  
an address  
the inter-

net can  
route to.  
Putting it  
there is  
called de-  
ploying,  
and that is  
chapter  
16. ir-  
globe an-  
swers at  
three in  
the morn-  
ing be-  
cause it is  
not on my  
laptop.

build  
?

One  
builds  
pages in  
memory  
for you.  
The oth-  
er  
writes  
the  
folder  
your  
users  
get.

Localhost  
turned out  
to be a  
name your  
machine  
uses for it-  
self. The  
other half  
of the ad-  
dress is  
still unex-  
plained,  
because  
something  
is answer-  
ing at that  
door, and  
in a  
framework  
project  
that some-  
thing is  
npm run  
dev.

You  
have run  
that com-  
mand a  
thousand  
times  
without  
wondering  
what it is.  
Sitting  
next to it  
in the  
same file  
there is  
npm run  
build. It  
takes

much  
longer and  
produces a  
folder you  
have prob-  
ably never  
opened.  
That fold-  
er is the  
part your  
users get.

What is  
running  
when you  
run npm  
run dev?

What runs  
is a pro-  
gram sit-  
ting in  
your ter-  
minal and  
waiting to  
be asked  
for things,  
the same  
way  
python3 -  
m  
http.server  
did in  
chapter 1.  
This one is  
far clever-  
er about

what it  
hands  
over.

Go to  
the terminal where  
it says  
ready and  
press Ctrl  
and C.  
Refresh  
the browser.  
The  
site is  
gone and  
the error  
is a refused connection,  
which  
means  
nothing is  
listening  
at that  
door any  
more.

Now  
start it  
again and  
open the  
project  
folder,  
looking for  
the HTML  
that arrived in  
the browser.  
There  
is no such  
file. Your  
project

has a src  
folder full  
of compo-  
nents and  
not one of  
them is a  
page.

Nothing  
on the  
disk  
matches  
what you  
saw in  
view  
source.

The  
dev server  
built that  
page in  
memory  
the mo-  
ment your  
browser  
asked for  
it and  
then let it  
go. Its  
whole job  
is to read  
the source,  
work out  
what the  
browser  
needs  
right now  
and hand  
it over.  
Then it  
watches  
the files so  
it can do

the same  
thing the  
instant  
you save.  
Nothing  
was writ-  
ten down,  
so a save  
appears in  
the brows-  
er in un-  
der a  
second.

What  
does the  
build do?

It takes a  
while,  
where the  
dev server  
started in-  
stantly.  
When it  
finishes  
there is a  
new folder  
called dist  
on Vite  
and .next  
on Next.js.  
Go in  
there with  
the com-

mands  
from chapter 2.

```
cd dist
ls -F
```

The HTML that did not exist a minute ago is in there. So are the scripts, with names like index-4f3a9c.js. Those characters in the middle are there so a browser can safely keep an old copy without mistaking it for the new one after you deploy. The CSS from every component in the project has been

gathered  
into one  
file.

Your  
source is  
written in  
whatever  
shape lets  
you work.  
This folder  
is written  
for  
browsers,  
in one  
shape and  
once. The  
dev server  
had been  
standing  
in for it on  
demand  
without  
ever writ-  
ing a word  
of it to  
disk.

Which  
one gets  
deployed?

The folder  
gets de-  
ployed,  
never your  
source and  
never the  
dev server.  
Deploying

means  
building  
that folder  
and  
putting its  
contents  
somewhere  
that an-  
swers re-  
quests all  
day, so a  
visitor is  
handed a  
finished  
file instead  
of waiting  
for a pro-  
gram to  
work one  
out.

You  
can serve  
that folder  
yourself  
right now.

```
cd dist
python3
```

Open lo-  
calhost:80  
00. That is  
your site,  
coming  
out of a  
plain file  
server that  
has never  
heard of  
your  
frame-

work. It is  
the same  
server that  
handed  
you one  
line of  
HTML in  
chapter 1.

Why do  
the two  
behave  
different-  
ly?

'Same  
code, same  
project, so  
it will be-  
have the  
same way,'  
you may  
be think-  
ing. Open  
one of  
those  
scripts in  
dist and  
read it.  
Your func-  
tion names  
are gone,  
replaced  
by single  
letters.  
The spaces  
are gone.

The whole  
file is one  
line.

The  
dev server  
is opti-  
mised for  
you. It  
starts in-  
stantly  
and re-  
freshes in-  
stantly,  
keeps your  
variable  
names so  
errors stay  
readable,  
and  
squashes  
nothing.

The build  
is opti-  
mised for  
the visitor,  
so it  
makes the  
smallest  
files it can,  
squashes  
everything  
together,  
drops code  
that noth-  
ing uses  
and short-  
ens every  
name it  
can reach.

Squashi  
ng changes  
behaviour.  
Code that  
quietly re-  
lied on a  
function  
still hav-  
ing its  
own name  
breaks, be-  
cause the  
name is  
gone and  
you just  
read the  
file where  
it went  
missing. A  
value read  
while the  
build is  
running  
gets frozen  
into the  
file, so  
changing  
it on the  
server af-  
terwards  
changes  
nothing  
until you  
build  
again, and  
chapter 13  
is about  
the trou-  
ble that  
causes. A  
file the

dev server  
found by  
walking  
your folder  
is missing  
from the  
output en-  
tirely if  
nothing  
imported  
it  
properly.

So a  
project  
can run  
beautifully  
for weeks  
and fall  
over on  
the first  
deploy  
without a  
line of  
source  
having  
changed.

When  
somebody  
says it  
works on  
my ma-  
chine they  
are usually  
telling the  
truth, be-  
cause their  
machine  
was run-  
ning the  
friendly  
version.

Before  
you de-  
ploy, run  
the build  
and serve  
the output  
locally the  
way you  
just did,  
then click  
around  
your own  
site.

Anything  
broken in  
that folder  
is broken  
in produc-  
tion, and  
you get to  
find it  
while you  
are sitting  
in front of  
it.

☐ my  
project  
passes  
this  
check

Chapter 5  
goes to  
the shop  
front and  
the till.  
What a  
backend  
is, and  
why some  
things can  
never live  
in the files  
you just  
looked at  
however  
well you  
hide them.

why  
does  
the  
till  
stan  
d in  
a  
dif-  
fer-  
ent  
roo  
m?

Everythi  
ng de-  
livered  
to the  
browser  
belongs  
to who-  
ever is  
standing  
there.

---

Everythin  
g so far  
has hap-  
pened in  
one room.  
Files ar-  
rive and  
the brows-  
er draws

them. You  
have now  
read your  
own  
project  
the way a  
visitor  
reads it. A  
shop has a  
second  
room be-  
hind the  
counter  
where the  
till and  
the keys  
are, and  
nobody  
has to be  
told why.  
In a  
project  
both  
rooms  
look like  
folders sit-  
ting next  
to each  
other in  
the same  
editor, so  
the till  
ends up  
out on the  
shop floor.

Which  
room is

the  
browser?

The  
browser is  
the front  
one and  
everything  
in it be-  
longs to  
whoever is  
standing  
there.

Every  
file that  
arrived is  
listed in  
the  
Network  
panel and  
you can  
click any  
of them  
and read  
it, includ-  
ing the  
scripts you  
wrote.

That will  
not be  
patched  
one day,  
because it  
is what  
delivery  
means.

'My  
code is  
minified,  
so nobody

can read  
it,' you  
may be  
thinking.  
Open one  
of your  
own  
scripts in  
that panel  
and find  
the button  
marked  
with  
braces at  
the bot-  
tom of the  
view. The  
one line  
becomes  
readable  
code  
again.  
Squashing  
a script  
makes the  
file smaller  
and it  
hides  
nothing.

What is a  
backend?

A backend  
is a pro-  
gram on  
another  
machine  
that an-

swers re-  
quests. It  
runs some-  
where else  
and listens  
at a door.  
You talk  
to it by  
sending  
exactly  
the kind of  
request  
you  
watched  
arrive in  
chapter 1.

The  
customer  
orders and  
the  
kitchen  
cooks. The  
customer  
does not  
come into  
the  
kitchen,  
because  
the  
kitchen is  
a different  
room. A  
script run-  
ning in the  
browser is  
a locked  
cupboard  
standing  
in the din-  
ing room,  
and the

customer  
has all  
evening.

What is  
an API?

An API is  
the menu.  
A menu  
tells you  
what you  
may order  
and in  
what  
form. An  
API tells  
you which  
requests  
the  
kitchen ac-  
cepts,  
meaning  
this ad-  
dress with  
this  
method  
and these  
fields.

Anything  
not on the  
menu is  
refused.

Writing  
one is the  
act of de-  
ciding  
what

strangers  
may ask  
you for.

The  
verbs on  
that menu  
are the  
methods.

GET  
fetches  
something,  
POST  
sends  
something  
new, PUT  
replaces,  
DELETE  
removes.

A GET is  
under-  
stood  
every-  
where to  
only fetch  
and search  
crawlers  
act on  
that un-  
derstand-  
ing. That  
is how a  
link which  
deletes a  
row gets  
triggered  
by a  
crawler  
that was  
only look-  
ing  
around.

What do  
the num-  
bers  
mean?

Every an-  
swer  
comes  
back with  
a status  
number  
and MDN  
carries the  
definitions  
if you  
want them  
properly.

200  
means it  
worked.  
404 means  
the  
kitchen  
under-  
stood you  
perfectly  
and has no  
such dish.  
500 means  
the  
kitchen  
broke  
while  
cooking,  
so the  
fault is on  
their side.

The  
two that  
get con-

fused constantly are  
401 and  
403. A 401  
means the  
kitchen  
does not  
know who  
you are,  
while a  
403 means  
it knows  
exactly  
who you  
are and re-  
fuses any-  
way.

Identity  
and per-  
mission  
are sepa-  
rate sys-  
tems with  
separate  
fixes, and  
telling  
them  
apart is  
the whole  
of chapter  
26.

Can you  
break

your own  
rule?

Find  
something  
in your  
own  
project  
that the  
page refus-  
es to let  
you do. A  
submit  
button  
that stays  
disabled  
until the  
form is  
valid, a  
field with  
a maxi-  
mum  
length, a  
section  
that only  
appears  
when you  
are logged  
in.

Anything  
the page  
decides.

Open  
the devel-  
oper tools  
and go to  
the  
Console  
tab. Then  
type one

of these,  
matching  
whichever  
rule you  
found.

The but-  
ton is live.  
The field  
takes as  
much as  
you want.  
You did  
not find a  
hole in  
your code,  
you re-  
typed a  
line of it,  
and every  
visitor has  
the same  
console  
you just  
used.

That is  
why a  
check  
written  
into your  
page is a  
suggestion.  
Your  
script runs  
on their  
machine.  
A check  
that holds

has to run  
in a room  
they can-  
not reach,  
which is  
the room  
this chap-  
ter is  
about.

Where  
does the  
key go?

Into the  
kitchen  
and never  
into a re-  
quest the  
customer  
can read.

stitchu  
sends a  
photo-  
graph to a  
vision  
model and  
that mod-  
el charges  
per call.  
The key  
that pays  
for it be-  
longs in  
the till, so  
the brows-  
er never  
holds it.  
The pho-

tograph  
goes to a  
Cloudflare  
Worker,  
the  
Worker  
holds the  
key and  
calls the  
model,  
and the  
answer  
comes  
back.  
Anyone  
can open  
the  
Network  
panel on  
stitchu  
and read  
every re-  
quest that  
leaves  
their ma-  
chine and  
find noth-  
ing in  
them to  
take.

The  
wrong ver-  
sion is one  
line of dif-  
ference.  
The  
browser  
calls the  
model di-  
rectly with  
the key at-

tached to  
the re-  
quest. It  
works on  
the first  
try (which  
is the  
trouble)  
because  
from be-  
hind the  
counter  
both ver-  
sions look  
the same  
to you.  
Every visi-  
tor now  
holds a  
working  
key billed  
to your ac-  
count, and  
chapter 31  
is about  
the size of  
that bill.

☐ my  
project  
passes  
this  
check

Chapter 6  
goes to  
where  
data lives,  
and why a  
file works  
perfectly  
until two  
people use  
your  
project at  
the same  
time.
